ABSTRACT

A survey was conducted in the year 2019-20 in old Mahboobnagar and Nalgonda district of Telangana state to study the characters of calcareous soils, based on effervescence with dilute HCl the samples were collected and were analysed for its characters. Majority of soils collected were medium to high in CaCO_3 status. All the soils collected were alkaline to highly alkaline in reaction. Soils were low to medium in available nitrogen and phosphorus content. The average pH, N, P_2O_5 , K_2O value recorded in these soils were 8.49, 77.19 kg ha^{-1} , 6.215 kg ha^{-1} , 72.88 kg ha^{-1} respectively. The main objective of the study is to know the properties of Calcereous soil and also to study the effect of calcium carbonate on the different properties of soil and therefore a correlation study was conducted which reported that there is significant positive relationship is seen between CaCO_3 content and pH and significant negative relationship is seen between CaCO_3 content and available N and P_2O_5 in soil. No significant relationship is seen between CaCO_3 content and EC and OC values.

1. INTRODUCTION

Calcareous soils are soils rich of calcium carbonate which occur mainly in the arid and semi-arid subtropics of both hemispheres. The diagnostic horizon in the calcareous soil is the calcic horizon which contains more than 15% CaCO₃ and has a depth of more than 15 cm thick. Potential productivity of calcareous soils is relatively high where adequate water and nutrients can be supplied. Crusting of the surface may affect not only infiltration and soil aeration but also the emergence of seedlings. Cemented conditions of the subsoil layers may hamper root development and water movement characteristics.

Many scientists discussed the definition of Calcareous soils as soils which contains high levels of calcium carbonate (CaCO₃) that affects soil properties related to plant growth, such as soil water relations and the availability of plant nutrients. Calcareous soils are common in the arid areas of the earth [1] occupying >30% of the earth's surface, and their CaCO₃ content varies from just detectable up to 95% [2]. Calcareous soils are the soils in which a high amount of calcium carbonate dominates the problems related to agricultural land use [3,4]. They are characterized by the presence of calcium carbonate in the parent material and by a calcic horizon, a layer of secondary accumulation of carbonates (usually Ca or Mg) in excess of 15% calcium carbonate equivalent and at least 5% more carbonate than an underlying layer. In the World Reference Base (WRB) soil classification system calcareous soils may mainly occur in the Reference Soil Group of *Calcisol*s.

Calcareous soils are common in arid and semi-arid climates affecting over 1.5 billion acres of land worldwide [5,6]. These soils are identified on the basis of presence of the mineral calcium carbonate in the parent material and an accumulation of lime. Calcite and aragonite (CaCO₃), dolomite [CaMg (CO₃)₂] and Magnesite (MgCO₃) are the calcium and magnesium carbonate minerals found in calcareous soils. They are mainly present as calcite, and to a lesser extent as dolomite. It is most easily recognized by the effervescence or fizz that occurs when these soils are treated with dilute acid [7] and (Soil Science Society of America, 1997). The pH of these soils is usually above 7.0 and may be as high as 8.5 [8]. When such soils

contain sodium carbonate, the pH may exceed 9.0. Calcareous soils are classified in to four classes based on the presence of calcium carbonate percent in them and they are slight (0-5%), moderate (5-10%), high (10-20%) and very high calcareous soils (20-25%). Calcareous soils are productive for agricultural use when they are managed properly.

2. MATERIALS AND METHODS

The survey work was conducted during 2019-2020 to collect representative surface soil samples of different calcareous soils in old Mahaboobnagar and Nalgonda district of Telangana state. On the field dilute HCl was applied with the help of dropper, the soils which has effervescence were subjected to chemical analysis and categorized into slightly, moderately and strongly calcareous soils with respect to per cent calcium carbonate status.

2.1 Soil Sample Collection and Chemical Analysis

The collected samples were air-dried, ground and passed through a 2 mm sieve and stored in polythene bags for further analytical work. The pH and EC of soils was measured in 1:2.5 soil water suspension using a glass electrode and Conductivity Bridge, respectively [9]. The organic carbon content of the soil was estimated by Walkley and Black's wet oxidation method as described by Jackson, 1973. Calcium carbonate in soil was determined by rapid acid titration method. The available nitrogen was determined by alkaline potassium permanganate method and Available phosphorus in soil was extracted by Olsen's extractant and Available potassium were extracted with neutral normal ammonium acetate solution and using flame photometer.

3. RESULTS AND DISCUSSION

Characters of different samples calcareous soils of Mahaboobnagar and Nalgonda is given in Table 1 and Table 2 respectively.

The percent of calcium carbonate in the soil samples collected from Mahaboobnagar and Nalgonda district ranged from 4.90 (lowest) to 14.58 (highest) and 4.93 (lowest) to 14.00 (highest) respectively. The CaCO₃ content variation in these soils may be due to parent material, native CaCO₃ content in soil profile and

faulty agricultural practices. Similar reports regarding the presence of calcium carbonate content in vertisols were reported by Halajinla et al. [10]. According to categorisation 30 soil samples collected are slight calcareous, 45 are moderately calcareous and remaining 50 were highly calcareous, mean value for CaCO_3 content is 9.63 in Nalgonda district whereas in Mahaboobnagar district 13 were slightly Calcareous, 54 were moderately Calcareous and 58 were highly Calcareous soils with mean value of 8.65.

All calcareous soils were alkaline in nature with pH value ranging from 7.91 to 9.07 with the average value of 8.44 and 7.84 to 9.16 with average of 8.65 in Nalgonda and Mahaboobnagar respectively. Being predominated by calcium carbonate, it was logical that pH of these soils were alkaline. Similar analytical result for soil pH in calcareous soils was reported by Afif et al. [11]. Organic carbon percent for these soils remained low to medium 0.04 to 1.62 % in Mahaboobnagar and 0.22 to 1.53 % in Nalgonda district due to insufficient availability of organic manures. The average OC value is 0.63 % in Nalgonda and 0.68 % in Mahaboobnagar district.

The highest available nitrogen content in soils was 42.70 kg ha^{-1} to 616 kg ha^{-1} in Nalgonda and 131 kg ha^{-1} to 450 kg ha^{-1} in Mahaboobnagar with the average values of 206 kg ha^{-1} and 204 kg ha^{-1} respectively in Mahaboobnagar and Nalgonda respectively , majority of the soils were belongs to category of low to medium in available nitrogen. The poor status of soil organic carbon resulted in low status of available nitrogen. The available phosphorus ranged from 13.40 to 37.20 kg ha^{-1} in Nalgonda and 12.30 to 38.90 in Mahaboobnagar with average value of 19.75 kg ha^{-1} from Mahaboobnagar and 22.30 from Nalgonda implies that majority of the soils were low to medium in available phosphorus. It may due to phosphorus fixation as Ca-P in soil resulted in low status of phosphorus. Similar result of low availability of phosphorus in calcareous soils was reported by Mostashari et al. 2008. Maximum available potassium recorded was $422.49 \text{ kg ha}^{-1}$; minimum available potassium recorded was 89.2 kg ha^{-1} average of 221.9 kg ha^{-1} in Mahaboobnagar and Maximum available potassium recorded was $396.49 \text{ kg ha}^{-1}$; minimum available potassium recorded was 150 kg ha^{-1} average of $245.38 \text{ kg ha}^{-1}$ in Nalgonda.

To study the effect of calcium carbonate on the different properties of soil and therefore a correlation study was conducted. The correlation analysis indicated significant positive relationship between CaCO_3 content and pH values. The correlation values (r) for a Mahaboobnagar and Nalgonda are presented in the Tables 3 and 4 respectively. As the CaCO_3 value increases there is increase in pH value is observed. This is because of the dissolution of excess CaCO_3 present in these soils, results in a high solution HCO_3^- concentration, that buffers the soil in the pH range of 7.5 to 8.5 [12]: as $\text{CaCO}_3 + \text{H}_2\text{O} \leftrightarrow \text{Ca}^{2+} + \text{HCO}_3^- + \text{OH}^-$.

There is significant negative relationship is seen between CaCO_3 content and available nitrogen and available P, because as the CaCO_3 content increases, the pH value will also increase (Tables 3 & 4). The alkaline pH values affects the rates of N transformations, which in turn can influence the efficiency of N use by plants [13] and at higher pH values, phosphate anions react with Ca and Mg to form phosphate compounds of limited solubility reported by Mortedt [14]. Maximum availability to plants of both native and applied P is in the pH range of 6.0 to 7.5. There is no significant relationship is seen between EC, OC and available K. in Mahaboobnagar whereas in Nalgonda, a positive and significant correlation was found between CaCO_3 and PH, EC, OC; negative and significant between relationship CaCO_3 and N,P,K.. As mentioned above high pH values affects the nutrient availability.

4. CONCLUSION

Majority of the soil samples collected were medium to high in calcium content. All of the samples collected (Slightly, moderately and strongly calcareous soils) were alkaline in reaction. These soils were slightly saline to saline and organic carbon status of these calcareous soils remained low to medium. Different type of calcareous soils belongs to low to medium in available nutrients i.e., N, P, K content. Slightly calcareous soils had relatively more available nutrients (N, P, K,) compare to moderately and strongly calcareous soils. OC and EC values remained unaffected by CaCO_3 content.
